Magnets

Objective  To gain experience implementing classes and methods.

The Scenario  This week, you will write a program to simulate the action of two bar magnets. Each magnet is represented by a simple rectangle with one end labeled “N” for north and the other labeled “S” for south. Your program allows the user to move either magnet around the screen by dragging it with the mouse. As with real magnets, opposite poles attract, while similar poles repel each other. If one magnet is dragged to a position where one or both of its poles is close to the similar poles of the other magnet, the other magnet moves away as if repelled by magnetic forces. On the other hand, if opposite poles come close to one another, the free magnet moves closer and becomes stuck to the magnet being dragged. A magnet can be flipped from end to end (swapping the poles) by clicking on it. This provides a way to separate two magnets if they get stuck together (since as soon as one of them is reversed it will repel the other).

See the handouts web page for a demo. We will also provide a starter project. It is described in the “Getting Started” section below.

Note: You must bring a program design to lab this week!

How it Will Work

Do not worry if you do not remember (or never knew) the details of magnetic fields. We will provide most of the code that does the “physics.” Even if you had to write all the code yourself, you still would not need a deep knowledge of magnetism and mechanics. Instead, you could exploit something every special effects expert or video game author knows: most people observe the world carelessly enough that even a very coarse approximation of reality will appear “realistic.” Our code takes advantage of this by simplifying the behavior of our magnets. We never compute the force between two magnets, just the distance between them. If they move too close together, our code moves them apart or makes them stick together. We assume magnets cannot be rotated; They only slide up, down and across the screen.

There is one aspect of the behavior of the real magnets that we must model well. Above, we said that we just compute the distance between two magnets. This would not really be accurate enough, since it is not just the distance between the magnets that matters, but also the distances between their similar and opposite poles.

Consider the two pairs of magnets shown below:

The magnets shown in the left pair are the same distance apart as the magnets in the right pair. In the pair on the left, however, the opposite poles are close together while the similar poles are relatively
far apart. The situation is reversed in the other pair. In the case on the left, one would expect the magnets to attract, and in the case on the right, to repel. So it is the poles rather than the magnets that really matter when deciding whether something should be attracted or repelled. As a result, instead of just manipulating magnet objects in your program, you will also need objects that explicitly represent poles.

We will help you design this program by identifying the classes and methods needed. In particular, you will need two classes: Magnet and Pole. Additionally, you will need a class that is an extension of WindowController. We will provide the code for the Pole class. You will write the other two class definitions.

### The Pole Class

You will use the provided Pole class in much the same way as the built-in graphics classes. In this handout, we explain how to construct a new Pole and describe the methods used to manipulate Poles. You can then write code to work with Poles just as you wrote code to work with FilledRects. We will see, however, that the interaction of Poles with the rest of your program is a little more complex than that of rectangles.

A Pole’s constructor requires you to specify the coordinate position at which it should initially appear and the label that should be displayed (i.e., “N” or “S”). It also requires you to provide as parameters the canvas and the Magnet to which the new pole will belong. The signature of the constructor for the Pole class is thus:

```java
public Pole(Magnet parent, double x, double y, String poleName, DrawingCanvas canvas)
```

Since you will usually create the Poles within the code of the Magnet constructor, the name this will refer to the Magnet that contains the Pole. Thus, the code to construct a Pole might look like:

```java
public Magnet(…formal parameters…) {
…
    northPole = new Pole(this, poleX, poleY, "N", canvas);
…
}
```

where poleX and poleY are the coordinates at which the label “N” should be displayed.

The Pole class provides several methods similar to those associated with graphical objects. In particular, Pole’s methods include getX, getY, getLocation, and move, all of which behave like the similarly named methods associated with basic graphic classes.

In addition, the Pole class has two more specialized methods: attract and repel. Each of these methods expects to be passed the Pole of another magnet as a parameter. If you say,

```java
somePole.attract(anotherPole)
```

then somePole and anotherPole should have opposite polarities. If somePole is a north pole, then anotherPole must be a south pole and vice versa. The repel method, on the other hand, assumes that the pole provided as its parameter has the same polarity as the object to which the method is applied. Therefore, if you write:

```java
somePole.repel(anotherPole)
```

and somePole is a north pole, then anotherPole should also be a north pole.

Each of these methods checks to see if the two Poles involved are close enough together to exert enough force to move the magnets to which they belong. If so, they use the move and moveTo methods.
of the magnets to either bring the magnets closer together or move the free magnet so that they are far enough apart that they would no longer interact.

The good news is that we have already written the code for all the methods described above and will provide these methods to you.

In summary, the Pole class provides the following methods. Note that we have given you complete method signatures (or headers) here, illustrating the format to follow in defining your own methods. Think carefully about how you will invoke each of the following methods.

- public double getX()
- public double getY()
- public Location getLocation()
- public void move(double xoff, double yoff)
- public void attract(Pole opposite)
- public void repel(Pole similar)

Do not modify the provided Pole class!

Implementation Strategy

Step 1: Basic Magnets  For the first part of this program, you should focus on creating the magnets and moving them around. We’ll consider their interactions (attracting and repelling) later. To reinforce the notion that preparing for your lab section greatly increases the value of the time spent in lab, we want you to come to lab with a written design.

The key to this lab is the design of the Magnet class. A magnet is represented by a FramedRect and two poles. To ensure that our Poles work well with your Magnets, each magnet should be 150 by 50 pixels. The poles should be located near each end of the magnet. We recommend locating them so the distance from the pole to the closest end, top, and bottom, are all 1/2 the height of the magnet (i.e. 25 pixels away from each).

Your Magnet class will provide methods that enable someone running your program to drag magnets around within a window. The Magnet class should include the following methods:

- public void move(double xoff, double yoff)
- public void moveTo(Location point)
- public Location getLocation()
- public boolean contains(Location point)

The signatures for these methods are already included in the starter file for the Magnet class. These methods should behave just like the corresponding methods for rectangles and ovals. In particular, the offsets provided to the move method are doubles, someMagnet.getLocation() should return a Location value, and someMagnet.contains(point) should return a boolean. You will add other methods later, but we’ll postpone discussing them until you need them.

To write these methods, your magnet needs to contain several instance variables. A magnet consists of a rectangle and two poles, so you will need instance variables for each of those. The Magnet constructor needs the following parameters:

- Coordinates of the upper-left corner of the magnet.
- The canvas that will hold the magnet.

The signature of the Magnet constructor should be:
public Magnet(Location upperLeft, DrawingCanvas canvas)

It should construct the framed rectangle forming the outline of the magnet (using the parameters) and the two poles in the correct positions inside the magnet (see the earlier discussion on the constructor for Pole).

Once these instance variables have been declared and initialized, write the methods for the Magnet class. The move and moveTo methods should move the rectangle and poles to their new positions. The move method is pretty straightforward as all three items get moved the same distance, but moveTo takes a little thought as the Pole class does not have a moveTo method. Instead you will need to calculate how far to move it. (Hint: check to see how far the rectangle is moving from its current position.) The method getLocation should return the location of the rectangle. A magnet contains a point exactly when the rectangle does.

Your program is not complete yet, but you should test your Magnet class before going on. To do this, you need to write a controller. We provide you with the stub of a WindowController class MagnetGame. To start, have MagnetGame create and store a single magnet. Then write methods onMousePress, onMouseDrag, and onMouseRelease that allow you to drag it around.

Once onMousePress, onMouseRelease, and onMouseDrag work, you should add a second magnet. We suggest declaring a variable (movingMagnet) that can be associated with the appropriate magnet and used to remember which magnet to move whenever the mouse is dragged. This variable will be useful in other parts of your project later.

While writing the methods for the Magnet class, you probably noticed that two additional methods are already included there. They are getWidth and getHeight. These are used by the Pole class in ensuring that the methods attract and repel draw the magnets appropriately in the window.

Preparing Your Design Before Lab: As mentioned earlier, you should bring a design with you to lab. The design should show us how you plan to organize your Magnet and MagnetGame classes to accomplish the actions required for “Step 1” of this lab only. We have told you what methods each class should have and the behavior that they should provide. You should write (in English, not Java) your plan for how each method will provide the necessary behavior. You should also describe (in English) what instance variables you feel are necessary for each class. This level of preparation will allow you to progress much more quickly in lab so that you can take better advantage of the presence of the instructors and TAs.

You may use the design template available on the handouts page (and attached to the end of this document) to help you organize your thoughts, as you did last week for the laundry lab. We would like you to fill out a design template for each of the two classes you will write: Magnet and MagnetGame. We have included at the end of this handout the design of the laundry lab as another example of a program design.

Step 2: Flipping the magnet When you click on a magnet, it should reverse its north and south poles. Add a flip method to the Magnet class that transposes the north and south poles. Remember that you can move a Pole, and one possible way to implement flip is to just move the north pole to the south pole's position and vice versa.

Add an onMouseClick method to your MagnetGame class that invokes flip.

Step 3: Interacting magnets Finally, after you move or flip a magnet, you will need to tell the magnet to check if it is close enough to the other magnet to move it. To make this possible, include a method named interact in your Magnet class. The method interact should be invoked on the moving (or changing) magnet, and should take as a parameter the Magnet that has not just been moved or flipped. It should effect the interaction by calling the attract and repel methods of its poles with the poles of the other magnet passed as parameters appropriately. For simplicity, you might want to work on attraction first, and only worry about repelling after the attraction works correctly.

When writing the interact method, you will discover that you need to add two more methods in the Magnet class to enable you to access the other magnet's poles: getNorth and getSouth. Both of these methods will return objects belonging to our Pole class. Also, note that the attract method
that we have provided in the Pole class calls the moveTo method that you must define in the Magnet class. If you do not fill in the body of this method correctly, attraction will not work properly.

You will need to call the interact method every time one of the magnets is either moved or flipped. Because you want to send the interact message to the magnet that moved and provide the other magnet as the parameter, you will need to keep track of which is which. As we suggested above, whenever you start dragging a magnet (i.e., in the onMousePressed method), you should associate a name with the moving magnet. You will also find it convenient to associate a name with the resting magnet in order to call your interact method appropriately.

When your program is finished, your Magnet class should have a constructor and method bodies implemented for getLocation, move, moveTo, and contains, for which signatures were provided. In addition, you will need to provide the methods interact, getNorth, getSouth, and flip. You should think carefully about the structure of the method signatures for each of these. To help you in formulating your ideas, the following give typical uses of the methods:

- `someMagnet.interact(otherMagnet);`
- `Pole theNorthPole = someMagnet.getNorth();`
- `Pole theSouthPole = someMagnet.getSouth();`
- `someMagnet.flip();`

---

**Getting Started**

To download the starter project, visit

http://www.cs.williams.edu/~cs134/

and then follow the link to the Handouts page. Click on the link for “Starter Code” under Lab 3.

This will download a file archive called Lab3Magnets.tar.gz to your cs134 folder. The files of this archive will then be extracted to a folder in your cs134 folder called Lab3Magnets. (If this does not happen automatically, simply double-click on the downloaded Lab3Magnets.tar.gz file to extract the archive.) You may delete the Lab3Magnets.tar.gz file at this point. Rename the “Lab3Magnets” folder to include your ID, as usual, and open the project folder in BlueJ.

The starter project contains several files intended to hold Java code. The file MagnetGame.java should be used to write the extension of the WindowController that will serve as your “main program.” The Magnet.java file should be used to hold your code for the Magnet class. Both of these files contain skeletons of the code that you need to complete. Finally, Pole.java holds our implementation of the Pole class. Remember, you should not change Pole.

---

**Submitting Your Work**

Once you have saved your work in BlueJ, please perform the following steps to submit your assignment:

- First, return to the Finder. You can do this by clicking on the smiling Macintosh icon in your dock.

- From the “Go” menu at the top of the screen, select “Connect to Server...”.

- For the server address, type in “afp://Guest@fuji” and click “Connect”.

- A dialog box will pop up. Connect as a guest by selecting the “Guest” option.

- A selection box should appear. Select “Courses” and click “OK”.

- You should now see a Finder window with a “cs134” folder. Open this folder by double clicking on it.
You should now see the drop-off folders for the three lab sections. Drag your “Lab3IDnnnn” folder into the appropriate lab section drop-off folder. When you do this, the Mac will warn you that you will not be able to look at this folder. That is fine. Just click “OK”.

Log off of the computer before you leave.

You can submit your work up to 11 p.m. on Wednesday if you’re in the Monday afternoon lab; up to 6 p.m. on Thursday if you’re in the Monday night lab; and up to 9 p.m. on Thursday if you’re in the Tuesday morning lab. If you submit and later discover that your submission was flawed, you can submit again. We will grade the latest submission made before your lab deadline. The Mac will not let you submit again unless you change the name of your folder slightly. It does this to prevent another student from accidentally overwriting one of your submissions. Just add something to the folder name (like the word “revised”) and the re-submission will work fine.

Grading Guidelines

As on all labs, we will evaluate your program for both style and correctness. Here are some specific items to keep in mind and focus on while writing your program:

Style
- Descriptive comments
- Good names
- Good use of constants
- Appropriate formatting

Logical Organization
- Good use of boolean expressions
- Not doing more work than necessary
- Using most appropriate methods

Correctness
- Drawing magnets correctly at startup
- Dragging a magnet
- Ability to move either magnet
- Moving a magnet to the right place when attracted
- On attraction, moving the magnet not pointed to
- Flipping a magnet
- Attracting and repelling at the right times
- No other problems
Quick Reference of the Pole Class

This section provides no new information. It is a quick reference to the constructor and methods provided in the Pole class that you will be using.

**Constructor**  To create a new pole:

```
public Pole(Magnet parent, double x, double y, String name, DrawingCanvas canvas)
```

**Example Usage**

```
Pole myPole = new Pole (this, xLoc, yLoc, "N", canvas);
```

**Accessor Methods**  To get information about a pole:

**Getting the x coordinate of the pole's center:**

```
public double getX()
```

**Example Usage**

```
double x = somePole.getX();
```

**Getting the y coordinate of the pole's center:**

```
public double getY()
```

**Example Usage**

```
double y = somePole.getY();
```

**Getting the coordinate pair of the pole's center:**

```
public Location getLocation()
```

**Example Usage**

```
Location loc = somePole.getLocation();
```

**Mutator Methods**  To modify a pole:

**Moving the pole relative to its current location:**

```
public void move(double xoff, double yoff)
```

**Example Usage**

```
somePole.move(xOffset, yOffset);
```

**Attracting another pole if close enough:**

```
public void attract(Pole oppositePole)
```

**Example Usage**

```
somePole.attract(anotherPole);
```

**Repelling another pole if close enough:**

```
public void repel(Pole similarPole)
```

**Example Usage**

```
somePole.repel(anotherPole);
```
Class Design Sheet

Class Overview

Name: Laundry Sorter  Superclass: Window Controller

Description:
A sorter for laundry that displays 3 baskets: white, color, dark - and a color swatch that is randomly chosen to be red, white, or black. The user must click on the right basket for the color, at which point a new color is chosen for the swatch.

Instance Variables

<table>

</table>
Constructors and Methods

| Signature: | public void begin() |
| Description: | Creates graphical objects for swatch & baskets. The swatch is initially white. |

| Code Outline: | - See layout at end. |
| | - Must set correct basket to white to reflect where the initial swatch should be put. |

| Signature: | public void onMouseClick (Location point) |
| Description: | Checks if the user clicked in the right basket, and changes the color if the user did. |

| Code Outline: | To switch color: |
| | - Get color using the random # generator |
| | - 1 means white, 2 means color, 3 means dark |
| | - Set correct basket to white if the number is 1 as well, and similarly for 2 and 3. |
| | - Uses a series of if statements |

| Signature: |
| Description: |

| Code Outline: |
Window Layout.
