Lecture 13

Fall 2017

Instructors: Bill & Bill

Administrative Details

- Mountain Day Madness!
 - All topics move one lecture earlier until M.D.
 - Problem Set 2 is online
 - Due 11:00pm, Thursday, Oct. 12 (in instructor's mail cubby)
- Reading Period Madness
 - Normal TA hours are in effect
 - Lab 5 will go online this weekend
 - Bring a design document to Lab on Wednesday
 - We'll begin collecting them again

Last Time

- The Comparable Interface
 - Including: how to write a generic static method
 - Generic Linear and Binary Search methods
- Basic Sorting
 - Bubble, Insertion, Selection Sorts

Today's Outline

- Basic Sorting Summary
- Comparator interfaces for flexible sorting
- More Efficient Sorting Algorithms
 - MergeSort
 - QuickSort

Basic Sorting Algorithms

- **BubbleSort**
 - Swaps consecutive elements of $a[0..k]$ until largest element is at $a[k]$; Decrements k and repeats
- **InsertionSort**
 - Assumes $a[0..k]$ is sorted and moves $a[k+1]$ across $a[0..k]$ until $a[0..k+1]$ is sorted
 - Increments k and repeats
- **SelectionSort**
 - Finds largest item in $a[0..k]$ and swaps it with $a[k]$
 - Decrements k and repeats

Basic Sorting Algorithms

(All Run in $O(n^2)$ Time)

- **BubbleSort**
 - Always performs cn^2 comparisons and might need to perform cn^2 swaps
- **InsertionSort**
 - Might need to perform cn^2 comparisons and cn^2 swaps
- **SelectionSort**
 - Always performs cn^2 comparisons but only $O(n)$ swaps

Lower Bound Notation

Definition: A function $f(n)$ is $\Omega(g(n))$ if for some constant $c > 0$ and all $n \geq n_0$

$$f(n) \geq c g(n)$$

So, $f(n)$ is $\Omega(g(n))$ exactly when $g(n)$ is $O(f(n))$

The previous slide says that all three sorting algorithms have time complexity

- $O(n^2)$: Never use more than $c n^2$ operations
- $\Omega(n^2)$: Sometimes use at least $c n^2$ operations

When $f(n)$ is $O(g(n))$ and $f(n)$ is $\Omega(g(n))$ we write

$$f(n) \text{ is } \Theta(g(n))$$

Comparators

- Limitations with Comparable interface
 - Only permits one order between objects
 - What if it isn't the desired ordering?
 - What if it isn't implemented?
- Solution: Comparators

Comparators (Ch 6.8)

- A comparator is an object that contains a method that is capable of comparing two objects
- Sorting methods can be written to apply a comparator to two objects when a comparison is to be performed
- Different comparators can be applied to the same data to sort in different orders or on different keys

```
public interface Comparator <E> {  
    // pre: a and b are valid objects  
    // post: returns a value <, =, or > than 0 determined by  
    // whether a is less than, equal to, or greater than b  
    public int compare(E a, E b);  
}
```

Example

```
class Patient {  
    protected int age;  
    protected String name;  
    public Patient (String s, int a) {name = s; age = a;}  
    public String getName() { return name; }  
    public int getAge() {return age;}  
}
```

Note that Patient does
not implement
Comparable or
Comparator!

```
class NameComparator implements Comparator <Patient>{  
    public int compare(Patient a, Patient b) {  
        return a.getName().compareTo(b.getName());  
    }  
} // Note: No constructor; a "do-nothing" constructor is added by Java
```

```
public void sort(T a[], Comparator<T> c) {  
    ...  
    if (c.compare(a[i], a[max]) > 0) {...}  
}
```

```
sort(patients, new NameComparator());
```

Comparable vs Comparator

- Comparable Interface for class X
 - Permits just one order between objects of class X
 - Class X must implement a compareTo method
 - Changing order requires rewriting compareTo
 - And recompiling class X
- Comparator Interface
 - Allows creation of “Comparator classes” for class X
 - Class X isn’t changed or recompiled
 - Multiple Comparators for X can be developed
 - Sort Strings by length (alphabetically for equal-length)

Selection Sort with Comparator

```
public static <E> int findPosOfMax(E[] a, int last,
    Comparator<E> c) {
    int maxPos = 0 // A wild guess
    for(int i = 1; i <= last; i++)
        if (c.compare(a[maxPos], a[i]) < 0) maxPos = i;
    return maxPos;
}

public static <E> void selectionSort(E[] a, Comparator<E> c) {
    for(int i = a.length - 1; i>0; i--) {
        int big= findPosOfMin(a,i,c);
        swap(a, i, big);
    }
}
```

- The same array can be sorted in multiple ways by passing different `Comparator<E>` values to the sort method;

Merge Sort

- A *divide and conquer* algorithm
- Merge sort works as follows:
 - If the list is of length 0 or 1, then it is already sorted.
 - Divide the unsorted list into two sublists of about half the size of original list.
 - Sort each sublist recursively by re-applying merge sort.
 - Merge the two sublists back into one sorted list.
- Time Complexity?
 - Spoiler Alert! We'll see that it's $O(n \log n)$
- Space Complexity?
 - $O(n)$

Merge Sort

- [8 14 29 1 17 39 16 9]
- [8 14 29 1] [17 39 16 9] split
- [8 14] [29 1] [17 39] [16 9] split
- [8] [14] [29] [1] [17] [39] [16] [9] split
- [8 14] [1 29] [17 39] [9 16] merge
- [1 8 14 29] [9 16 17 39] merge
- [1 8 9 14 16 17 29 39] merge

Transylvanian Merge Sort Folk Dance

Merge Sort

- How would we implement it?
- First pass...

// recursively mergesorts A[from .. To] “in place”

void recMergeSortHelper(A[], int from, int to)

if (from ≤ to)

mid = (from + to)/2

recMergeSortHelper(A, from, mid)

recMergeSortHelper(A, mid+1, to)

merge(A, from, to)

But *merge* hides a number of important details....

Merge Sort

- How would we implement it?
 - Review MergeSort.java
 - Note carefully how temp array is used to reduce copying
 - Make sure the data is in the correct array!
- Time Complexity?
 - Takes at most $2k$ comparisons to merge two lists of size k
 - Number of splits/merges for list of size n is $\log n$
 - Claim: At most time $O(n \log n)$...We'll see soon...
- Space Complexity?
 - $O(n)$?
 - Need an extra array, so really $O(2n)$! But $O(2n) = O(n)$

Merge Sort = $O(n \log n)$

- [8 14 29 1 17 39 16 9]
- [8 14 29 1] [17 39 16 9] split
- [8 14] [29 1] [17 39] [16 9] split } log n
- [8] [14] [29] [1] [17] [39] [16] [9] split
- [8 14] [1 29] [17 39] [9 16] merge
- [1 8 14 29] [9 16 17 39] merge } log n
- [1 8 9 14 16 17 29 39] merge

merge takes at most n comparisons per line

Time Complexity is $O(n \log(n))$

- Prove for $n = 2^k$ (true for other n but harder)
- That is, MergeSort for $n = 2^k$ performs at most
 - $n * \log(n) = 2^k * k$ comparisons of elements
- Base case: $k \leq 1$: 0 comparisons: $0 < 1 * 2^1$ ✓
- Induction Step: Suppose true for all integers smaller than k . Let $T(k)$ be # of comparisons for 2^k elements. Then
- $T(k) \leq 2^k + 2 * T(k-1) \leq 2^k + 2(k-1)2^{k-1} \leq k * 2^k$ ✓

Merge Sort

- Unlike Bubble, Insertion, and Selection sort, Merge sort is a divide and conquer algorithm
 - Bubble, Insertion, Selection sort complexity: $O(n^2)$
 - Merge sort complexity: $O(n \log n)$
- Are there any problems or limitations with Merge sort?
- Why would we ever use any other algorithm for sorting?

Problems with Merge Sort

- Need extra temporary array
 - If data set is large, this could be a problem
- Waste time copying values back and forth between original array and temporary array
- Can we avoid this?

Quick Sort

- Quick sort is designed to behave much like Merge sort, without requiring extra storage space

Merge Sort	Quick Sort
Divide list in half	Partition* list into 2 parts
Sort halves	Sort parts
Merge halves	Join* sorted parts

Recall Merge Sort

```
private static void mergeSortRecursive(Comparable data[],
                                       Comparable temp[], int low, int high) {
    int n = high-low+1;
    int middle = low + n/2;
    int i;

    if (n < 2) return;
    // move lower half of data into temporary storage
    for (i = low; i < middle; i++) {
        temp[i] = data[i];
    }
    // sort lower half of array
    mergeSortRecursive(temp,data,low,middle-1);
    // sort upper half of array
    mergeSortRecursive(data,temp,middle,high);
    // merge halves together
    merge(data,temp,low,middle,high);
}
```

Quick Sort

```
// pre: low <= high
// post: data[low..high] in ascending order
public void quickSortRecursive(Comparable data[],
                               int low, int high) {
    int pivot;
    if (low >= high) return;

    /* 1 - split with pivot */
    pivot = partition(data, low, high);
    /* 2 - sort small */
    quickSortRecursive(data, low, pivot-1);
    /* 3 - sort large */
    quickSortRecursive(data, pivot+1, high);
}
```

Partition

1. Put first element (pivot) into sorted position
2. All to the left of “pivot” are smaller and all to the right are larger
3. Return index of “pivot”

[Partition by Hungarian Folk Dance](#)

Partition

```
int partition(int data[], int left, int right) {
    while (true) {
        while (left < right && data[left] < data[right])
            right--;
        if (left < right) {
            swap(data, left++, right);
        } else {
            return left;
        }

        while (left < right && data[left] < data[right])
            left++;
        if (left < right) {
            swap(data, left, right--);
        } else {
            return right;
        }
    }
}
```

Complexity

- Time:
 - Partition is $O(n)$
 - If partition breaks list exactly in half, same as merge sort, so $O(n \log n)$
 - If data is already sorted, partition splits list into groups of 1 and $n-1$, so $O(n^2)$
- Space:
 - $O(n)$ (so is MergeSort)
 - In fact, it's $n + c$ compared to $2n + c$ for MergeSort

Merge vs. Quick

Food for Thought...

- How to avoid picking a bad pivot value?
 - Pick median of 3 elements for pivot (heuristic!)
- Combine selection sort with quick sort
 - For small n , selection sort is faster
 - Switch to selection sort when elements is ≤ 7
 - Switch to selection/insertion sort when the list is almost sorted (partitions are very unbalanced)
 - Heuristic!

Sorting Wrapup

	Time	Space
Bubble	Worst: $O(n^2)$ Best: $O(n)$ - if “optimiazed”	$O(n) : n + c$
Insertion	Worst: $O(n^2)$ Best: $O(n)$	$O(n) : n + c$
Selection	Worst = Best: $O(n^2)$	$O(n) : n + c$
Merge	Worst = Best: $O(n \log n)$	$O(n) : 2n + c$
Quick	Average = Best: $O(n \log n)$ Worst: $O(n^2)$	$O(n) : n + c$

More Skill-Testing (Try these at home)

Given the following list of integers:

9 5 6 1 10 15 2 4

- 1) Sort the list using Bubble sort. Show your work!
- 2) Sort the list using Insertion sort. . Show your work!
- 3) Sort the list using Merge sort. . Show your work!
- 4) Verify the best and worst case time and space complexity for each of these sorting algorithms as well as for selection sort.
