Data Structures &
Advanced Programming

Lecture 15

Fall 2017

Instructor: Bills

Announcements

- Mid-Term Review Session
 - Tonight (10/16), 8:00-9:00 pm in TPL 205
 - And Tuesday night---same time, same place
 - No prepared remarks, so bring questions!
- Mid-term exam is Wednesday, October 18
 - During your normal lab session
 - You'll have 1 hour & 45 minutes (if you come on time!)
 - Closed-book
 - Covers Chapters 1-7 & 9 and all topics up through sorting
 - A “sample” mid-term and study sheet are available online
 - [See Handouts & Problem Sets](#)

Last Time

- QuickSort and Sorting Wrap-Up
- Linear Structures
 - The Linear Interface (LIFO & FIFO)
 - The AbstractLinear and AbstractStack classes
- Stack Implementations
 - StackArray, StackVector, StackList,
- Stack applications
 - Expression Evaluation
 - PostScript: Page Description & Programming

Today: Linear Structures

- Stack applications
 - A Bit More PostScript
 - Mazerunning (Depth-First-Search)
- Queues
 - Implementations
 - Applications

Converting Expressions

- We (humans) primarily use “infix” notation to evaluate expressions
 - $(x+y)*z$
- Computers traditionally used “postfix” (also called Reverse Polish) notation
 - $xy+z*$
 - Operators appear after operands, parentheses not necessary
- How do we convert between the two?
 - Compilers do this for us

Converting Expressions

- Example: $x*y+z*w$
- Conversion
 - 1) Add full parentheses to preserve order of operations
 $((x*y)+(z*w))$
 - 2) Move all operators (+-*/) after operands
 $((xy*)(zw*)+)$
 - 3) Remove parentheses
 $xy*zw*+$

Use Stack to Evaluate Postfix Exp

- While there are input “tokens” (i.e., symbols) left:
 - Read the next token from input.
 - If the token is a value, push it onto the stack.
 - Else, the token is an operator that takes n arguments.
 - (It is known a priori that the operator takes n arguments.)
 - If there are fewer than n values on the stack \rightarrow error.
 - Else, pop the top n values from the stack.
 - Evaluate the operator, with the values as arguments.
 - Push the returned result, if any, back onto the stack.
 - The top value on the stack is the result of the calculation.
 - Note that results can be left on stack to be used in future computations:
 - Eg: $3\ 2\ *\ 4\ +$ followed by $5\ /$ yields 2 on top of stack

Example

- $(x*y)+(z*w) \rightarrow xy*zw*+$
- Evaluate:
 - Push x
 - Push y
 - Mult: Pop y, Pop x, Push $x*y$
 - Push z
 - Push w
 - Mult: Pop w, Pop z, Push $z*w$
 - Add: Pop $x*y$, Pop $z*w$, Push $(x*y)+(z*w)$
 - Result is now on top of stack

Preview: PostScript

- PostScript is a programming language used for generating vector graphics
 - Best-known application: describing pages to printers
- It is a stack-based language
 - Values are put on stack
 - Operators pop values from stack, put result back on
 - There are numeric, logic, string values
 - Many operators
- Let's try it: The 'gs' command runs a PostScript interpreter....
- You'll be writing a (tiny part of) gs in lab soon....

Preview: PostScript

- Types: numeric, boolean, string, array, dictionary
- Operators: arithmetic, logical, graphic, ...
- Procedures
- Variables: for objects and procedures
- PostScript is just as powerful as Java, Python, ...
 - Not as intuitive
 - Easy to automatically generate
- **Example: Recursive factorial procedure**
`/fact { dup 1 gt { dup 1 sub fact mul } if } def`
- **Example: Drawing (see picture.ps)**

Mazes

- How can we use a stack to solve a maze?
 - <http://www.primaryobjects.com/maze/>
- Properties of mazes:
 - We model a maze as a rectangular grid of cells
 - There is a *start* cell and one or more *finish* cells
 - Goal: Find path of *adjacent* free cells from *start* to *finish*
- Strategy: Consider unvisited cells as “potential tasks”
 - Use linear structure (stack) to keep track of current path being explored

Solving Mazes

- We'll use two objects to solve our maze:
 - Position: Info about a single cell
 - Maze: Grid of Positions
- General strategy:
 - Use stack to keep track of path from start
 - If we hit a dead end, backtrack by popping location off stack
 - Mark discarded cells to make sure we don't visit the same paths twice

Backtracking Search

- Try one way (favor north and east)
- If we get stuck, go back and try a different way
- We will eventually either find a solution or exhaust all possibilities
- Also called a “depth first search”
- Lots of other algorithms that we will not explore: <http://www.astrolog.org/labyrnth/algrithm.htm>

A “Pseudo-Code” Sketch

// Initialization

Read cell data (free/blocked/start/finish) from file data

Mark all free cells as unvisited

Create an empty stack S

Mark start cell as visited and push it onto stack S

While (S isn't empty && top of S isn't finish cell)

current \leftarrow *S.peek()* *// current is top of stack*

If (current has an unvisited neighbor x)

Mark x as visited ; S.push(x) *// x is explored next*

Else S.pop()

If finish is on top of S then success else no solution

Is Pseudo-Code Correct?

- Tools
 - Concepts: *adjacent cells; path; simple path; path length; shortest path; distance between cells; reachable from cell*
 - Solving a maze: is *finish* reachable from *start*?
- Theorem: The pseudo-code will either visit *finish* or visit every free cell reachable from *start*
- **Proof:** Prove that if algorithm does *not* visit *finish* then it *does* visit every free cell reachable from *start*
 - Do this by induction on distance of free cell from *start*
 - Base case: distance 0. Easy
 - Induction: Assume every reachable free cell of distance at most $k \geq 0$ from *start* is visited. Prove for $k+1$

Is Pseudo-Code Correct?

- Induction Hyp: Assume every reachable free cell of distance at most $k \geq 0$ from *start* is visited.
- Induction Step: Prove that every reachable free cell of distance $k+1$ from *start* is visited.
 - Let c be a free cell of distance $k+1$ reachable from *start*
 - Then c has a free neighbor d that is distance k from *start* and reachable from *start*
 - But then by induction, d is visited, so it was put on stack
 - So each free neighbor of d is visited by algorithm
- Done!

Recursive “Pseudo-Code” Sketch

Boolean RecSolve(Maze m, Position current)

If (current equals finish) return true

Mark current as visited

next ← some unvisited neighbor of current (or null if none left)

While (next does not equal null && recSolve(m, next) is false)

next ← some unvisited neighbor of current (or null if none left)

Return next ≠ null

- To solve maze, call: *Boolean recSolve(m, start)*
- To prove correct: Induction on distance from *current* to *finish*
- How could we generate the actual solution?

Implementing A Maze Solver

- Iteratively: Maze.java
- Recursively: RecMaze.java
 - Recursive method keeps an implicit stack
 - The method call stack
 - Each recursive call adds to the stack

Implementation: Position class

- Represent position in maze as (x,y) coordinate
- class Position has several relevant methods:
 - Find a neighbor
 - Position `getNorth()`, `getSouth()`, `getEast()`, `getWest()`
 - boolean `equals()`
 - Check states of position
 - boolean `isVisited()`, `isOpen()`
 - Set states of position
 - void `visit()`, `setOpen(boolean b)`

Maze class

- Relevant Maze methods:
 - `Maze(String filename)`
 - Constructor; takes file describing maze as input
 - `void visit(Position p)`
 - Visit position `p` in maze
 - `boolean isVisited(Position p)`
 - Returns true iff `p` has been visited before
 - `Position start(), finish()`
 - Return start /finish positions
 - `Position nextAdjacent(Position p)`
 - Return next unvisited neighbor of `p`---or null if none
 - `boolean isClear(Position p)`
 - Returns true iff `p` is a valid move and is not a wall

Method Call Stacks

- In JVM, need to keep track of method calls
- JVM maintains stack of method invocations (called frames)
- Stack of frames
 - Receiver object, parameters, local variables
- On method call
 - Push new frame, fill in parameters, run code
- Exceptions print out stack
- Example: StackEx.java
- Recursive calls recurse too far: StackOverflowException
 - Overflow.java

Recursive Call Stacks

```
public static long factorial(int n) {  
    if (n <= 1) // base case  
        return 1;  
    else  
        return n * factorial(n - 1);  
}
```

```
public static void main(String args[]) {  
    System.out.println(factorial(3));  
}
```
