## Announcements & Logistics

- CSI34 Scheduled Final: Wednesday, Dec II, 9:30 AM
  - Room: Wachenheim BII / Bronfman Auditorium
- CSI34 **Review Session** before Final:
  - Monday, December 9, time 10am
  - Room: **TPL 203**
  - SNACKS!

#### **Do You Have Any Questions?**

## CSI34 (Review): Jeopardy

## **Rules of the Game**

- The team in control of the board chooses a category and point value
  - Higher-point-value questions are more challenging
- ALL teams start working on the solution and when a team is done, a team member raises a hand holding their written solution
- We will begin counting and other teams may raise their solution before the count reaches '5'
  - All answers must be written down on a piece of paper
  - Once a solution is raised, it is final!
- All teams that answered correctly earn points
- The first team to raise their hand that had a correct answer gets control of the board
- All teams that answered incorrectly lose points

## **Game Board**

| Short &<br>Sweet | Predict the<br>Output | OOP | Loops and<br>Recursion | Potpourri |
|------------------|-----------------------|-----|------------------------|-----------|
| 2                | 2                     | 2   | 2                      | 2         |
| 3                | 3                     | 3   | 3                      | 3         |
| 5                | 5                     | 5   | 5                      | 5         |
| 7                | 7                     | 7   | 7                      | 7         |

## Short & Sweet for 2 Points

This Python type is most appropriate to store unordered values but it does not store duplicates.

## Short & Sweet for 3 Points

This expression from below DOES NOT give a TypeError. A.  $\{1: 'o'\} + \{2: 'h'\}$ B. len(77777) C. 3 in range(10)

## Short & Sweet for 5 Points

This is a one-line Python expression that converts 'a,b,c,d,e,f' to 'abcdef'.

## Short & Sweet for 7 Points

Given a list L of single-character digit strings, this is a one-line expression whose value is the integer that corresponds to concatenating the digits in reverse order, e.g., - if L is the list ['3', '4', '5'], the code should compute 543 - if L is the list ['5', '3', '7', '2'],

the code should compute 2735

#### **Predict the Output for 2 Points**

# This is the output printed by the following code:

## print(print("hello"))

#### **Predict the Output for 3 Points**

This is the output printed by the following code: x, y = 3, 8def f(): x, y = 6, 7**f()** print(x, y)

### **Predict the Output for 5 Points**

This is the output printed
by the following code:
t = ['5', '12', '3', '007']
print(sorted(t, key=int))

### **Predict the Output for 7 Points**

This is the output printed by the following code:

```
d = {1: {2: 3}, 4: {5: 6}}
s = 0
for k1 in d:
    for k2 in d[k1]:
        s += k1 + d[k1][k2]
print(s)
```

## **OOP for 2 Points**

This is the special method called when an instance of a class is created.

## **OOP for 3 Points**

This is the special expression that is used instead of self when invoking a method of a parent class.

## **OOP for 5 Points**

This is the attribute of Sample class that is not inherited by any of its subclass(es).

```
class Sample:
    def __init__(self, val1, val2, val3):
        self.a = val1
        self._b = val2
        self._c = val3
```

## **OOP for 7 Points**

This is printed when the following code is run:

class Test: def \_\_init\_\_(self): print(self)

def \_\_str\_\_(self):
 return "hello"

print(Test())

**Loops and Recursion for 2 Points** 

This is the Big O Complexity of the following recursive function.

def halves(n):
 if n > 0:
 print(n)
 halves(n//2)

**Loops and Recursion for 3 Points** 

This is printed when we run:

for i in range(2):
 for j in range(i):
 print(i, j)

#### **Loops and Recursion for 5 Points**

This shape is drawn by the following recursion:

def draw(len, sides):
 if sides > 0:
 fd(len); lt(90)
 draw(len, sides-1)

draw(10, 4)

#### **Loops and Recursion for 7 Points**

What is the iterative function that is equivalent to this recursive function:

def mystery(num\_lst):
 '''Assume num\_lst is a list of numbers'''
 if len(num\_lst) < 1:
 return 0
 else:
 return num\_lst[0] + mystery(num\_lst[1:])
 What is ....?</pre>

## Potpourri for 2 Points

For a data type to be used as a key in a dictionary, the data type must have this property.

## Potpourri for 3 Points

This is the Big O time complexity of an algorithm that compares each number in the list of numbers to every other number in the list (using a nested for loop) to determine if any pair adds up to a given target value.

## **Potpourri for 5 Points**

This is printed by the following code:

def optional(word, num=3):
 return word \* num

if \_\_name\_\_ == "\_\_main\_\_":
 print(optional("a") + optional("z", 2))

## **Potpourri for 7 Points**

This is the value of nums after this code is run:

nums = [1, 2, 3] new = nums new = new.append(4) nums.append(new) What is ....?
